

# Degree Under the Preferential Attachment (BA) Model

**Social Networks Analysis and Graph Algorithms**

Prof. Carlos “ChaTo” Castillo — <https://chato.cl/teach>

**Universitat  
Pompeu Fabra**  
*Barcelona*

# Contents

- Degree distribution under the BA model
- Distance distribution under the BA model
- Clustering coefficient under the BA model

BA model means Barabási-Albert model (preferential attachment)

# Sources

- Albert-László Barabási (2016) Network Science
  - Preferential attachment follows [chapter 05](#)
- [Ravi Srinivasan 2013 Complex Networks Ch 12](#)
- [Networks, Crowds, and Markets Ch 18](#)
- [Data-Driven Social Analytics](#) course by Vicenç Gómez and Andreas Kaltenbrunner

# Remember the BA model

- Network starts with  $m_0$  nodes connected arbitrarily as long as their degree is  $\geq 1$
- At every time step we add 1 node
- This node will have  $m$  outlinks ( $m \leq m_0$ )
- The probability of an existing node of degree to gain one such  $k_i$  link is

$$\Pi(k_i) = \frac{k_i}{\sum_{j=1}^{N-1} k_j}$$

# Degree $k_i(t)$ as a function of time

$$\frac{d}{dt}k_i = m\Pi(k_i) = m \frac{k_i}{\sum_{j=1}^{N-1} k_j}$$

$$\sum_{j=1}^{N-1} k_j = L(0) + 2m(t-1) \approx 2m(t-1)$$

$$\frac{d}{dt}k_i = \frac{mk_i}{2m(t-1)} = \frac{k_i}{2t-2} \approx \frac{k_i}{2t}$$

(For large  $t$ )

# Degree $k_i(t)$ ... continued

$$\frac{d}{dt} k_i(t) = \frac{k_i(t)}{2t}$$

$$\frac{1}{k_i(t)} \frac{d}{dt} k_i(t) = \frac{1}{2t}$$

$$\int_{t=t_i}^t \frac{1}{k_i(t)} \frac{d}{dt} k_i(t) dt = \int_{t=t_i}^t \frac{1}{2t} dt$$

Note: in exams for this course, you will **not** be asked to solve differential equations on your own

( $t_i$  is the creation time of node  $i$ )

$$\log k_i(t) - \log k_i(t_i) = \frac{1}{2} \log t - \frac{1}{2} \log t_i$$

$$\log k_i(t) = \frac{1}{2} \log t - \frac{1}{2} \log t_i + \log m$$

# Degree $k_i(t)$ ... continued

$$\log k_i(t) = \frac{1}{2} \log t - \frac{1}{2} \log t_i + \log m$$

$$k_i(t) = m \left( \frac{t}{t_i} \right)^{\frac{1}{2}}$$

**Is the degree growth linear, super-linear, or sub-linear? Intuitively, why?**

$$k_i(t) = m \left( \frac{t}{t_i} \right)^{\frac{1}{2}} = m \left( \frac{t}{t_i} \right)^{\beta}$$

$\beta = 1/2$  is called the dynamical exponent

# Degree $k_i(t)$ ... consequences

$$\log k_i(t) = \frac{1}{2} \log t - \frac{1}{2} \log t_i + \log m$$

$$k_i(t) = m \left( \frac{t}{t_i} \right)^{\frac{1}{2}}$$

$$\frac{dk_i(t)}{dt} = \frac{k_i(t)}{2t} = \frac{m \left( \frac{t}{t_i} \right)^{\frac{1}{2}}}{2t} = \frac{m}{2(t \cdot t_i)^{\frac{1}{2}}}$$

**If  $t_i < t_j$  (node  $i$  is older than node  $j$ ), what do we expect of  $k_i$  and  $k_j$ ?**

# Simulation results

Model

Nodes with  $t_i = 1, 10, 100, 1000, 10000, \dots$

# Degree distribution

- The distribution of the degree follows

$$p(k) \approx 2m^2/k^3$$

- Note that it does not depend on the time
- Hence, it describes a stationary network

# Degree distribution, simulation results

$N=100,000$      $m=3$

# More simulations

$N = 100,000$ ;  $m_0 = m =$

1 (blue), 3 (green), 5 (gray), 7 (orange)

Observe  $\gamma$  is independent of  $m$  (and  $m_0$ )

The slope of the purple line is -3

$m_0 = m = 3$ ;  $N =$

50K (blue), 100K (green), 200K (gray)

Observe  $p_k$  is independent of  $N$

# Average distance

- Distances grow slower than  $\log N$

$$\langle d \rangle \approx \frac{\log N}{\log \log N}$$

(Why: scale free network with  $\gamma = 3$ )

# Clustering coefficient

- BA networks are locally more clustered than ER networks

$$\langle C \rangle \approx \frac{(\log N)^2}{N}$$

# Limitations of the BA model

- Predicts a fixed exponent of -3
- Assumes an undirected network, while many real complex networks are directed
- Does not consider node deletions or edge deletions which are common in practice
- Considers that all nodes are equal except for their arrival times

# Summary

# Things to remember

- Degree distribution in the BA model
- Distances and clustering coefficient in BA

# Practice on your own

- Try to reconstruct the derivations we have done in class
  - Try to understand every step
- Insert a small change in the model and try to recalculate what we have done

**Additional contents**  
**(not included in exams)**

**EXTRA**

# Cumulative Distribution Function

Let's calculate the CDF of the degree distribution

By definition of CDF, this is equal to:

$$Pr(k_i(t) \leq k) = 1 - Pr(k_i(t) > k)$$

# CDF (cont.)

Let's calculate  $Pr(k_i(t) > k)$

$$k_i(t) = m \left( \frac{t}{t_i} \right)^\beta$$

$$k_i(t) > k \Rightarrow m \left( \frac{t}{t_i} \right)^\beta > k$$

$$m^{\frac{1}{\beta}} \left( \frac{t}{t_i} \right) > k^{\frac{1}{\beta}}$$

$$\left( \frac{m}{k} \right)^{\frac{1}{\beta}} \left( \frac{t}{t_i} \right) > 1$$

$$\left( \frac{m}{k} \right)^{\frac{1}{\beta}} > \left( \frac{t_i}{t} \right)$$

---

This means that nodes  $i$  with degree larger than  $k$  were created at time  $t_i$  **before** a certain timestep, which is expected because older nodes have larger degree.

$$t_i < t \left( \frac{m}{k} \right)^{\frac{1}{\beta}}$$

# CDF (cont.)

From the previous slide, we have:  $Pr(k_i(t) > k) = Pr\left(\left(\frac{m}{k}\right)^{\frac{1}{\beta}} > \frac{t_i}{t}\right)$

Remember there is one node created at each timestep, so by time  $t$  there are  $N(t) = m_o + t$  nodes, and for large  $t$ , we have  $N(t) \approx t$

Now, what is  $Pr(x > t_i/t)$  if you pick a node  $i$  at random?

It is  $x$ , because  $t_i/t$  is **distributed uniformly in  $[0,1]$**

Hence:

$$Pr(k_i(t) > k) = \left(\frac{m}{k}\right)^{\frac{1}{\beta}}$$

Imagine the following “game”, in which the larger number wins

- You pick a number  $x$  in  $[0,1]$
- Your opponent picks a number  $y$  uniformly at random in  $[0,1]$

The probability that  $x > y$  and hence you win is exactly  $x$

# CDF (cont.)

Hence:

$$\begin{aligned} Pr(k_i(t) \leq k) &= 1 - Pr(k_i(t) > k) \\ &= 1 - \left(\frac{m}{k}\right)^{\frac{1}{\beta}} \end{aligned}$$

# Probability Density Function (PDF)

Now let's take the derivative of the CDF to obtain the PDF

$$\begin{aligned} p_k &= \frac{d}{dk} \Pr(k_i \leq k) = \frac{d}{dk} \left( 1 - \left( \frac{m}{k} \right)^{1/\beta} \right) \\ &= -\frac{d}{dk} \left( \left( \frac{m}{k} \right)^{1/\beta} \right) = -m^{1/\beta} \frac{d}{dk} \left( \frac{1}{k^{1/\beta}} \right) \\ &= \frac{1}{\beta} \frac{m^{1/\beta}}{k^{1/\beta+1}} \quad (\beta = 1/2) \\ &= 2 \frac{m^2}{k^3} \longrightarrow p(k) \propto k^{-3} \end{aligned}$$

# Degree distribution

- $\beta = 1/2$  is called the dynamical exponent
- $\gamma = \frac{1}{\beta} + 1 = 3$  is the power-law exponent
- Note that  $p(k) \approx 2m^2/k^3$   
does not depend on  $t$   
hence, it describes a stationary network
