Types of centrality measure

- **Non-spectral**
 - Degree
 - Closeness and harmonic closeness
 - Betweenness
- Spectral
 - HITS
 - PageRank

Betweenness

Definitions

The **betweenness of an edge** is the number of shortest paths that cross that edge

The **betweenness of a node** is the number of shortest paths that cross that node

Example 1

There are 20 shortest paths that cross through node 3. Why?

The shortest path between nodes 1 and 2 does not cross node 3, but the shortest path between nodes 1 and 4 does cross node 3.

Example 2

Here, nodes and edges are labeled with their betweenness.

A: Degree

B: Closeness

C: Betweenness

D: PageRank

Edge Betweenness

An **edge** has high betweenness if it is part of many shortest-paths
... how to compute this efficiently?

Algorithm [Brandes, Newman]

- For every node u in V
 - Layer the graph performing a BFS from u
 - For every node v in V , $v \neq u$, sorted by layer
 - Assign to v a number $s(v)$ indicating how many shortest paths from u arrive to v
 - **For every node v in V , $v \neq u$, sorted by reverse layer**
 - Score to distribute = $1 + \text{score from children}$
 - Add score to parent edges in proportion to $s(v)$
- In the end divide all edge scores by two

Example

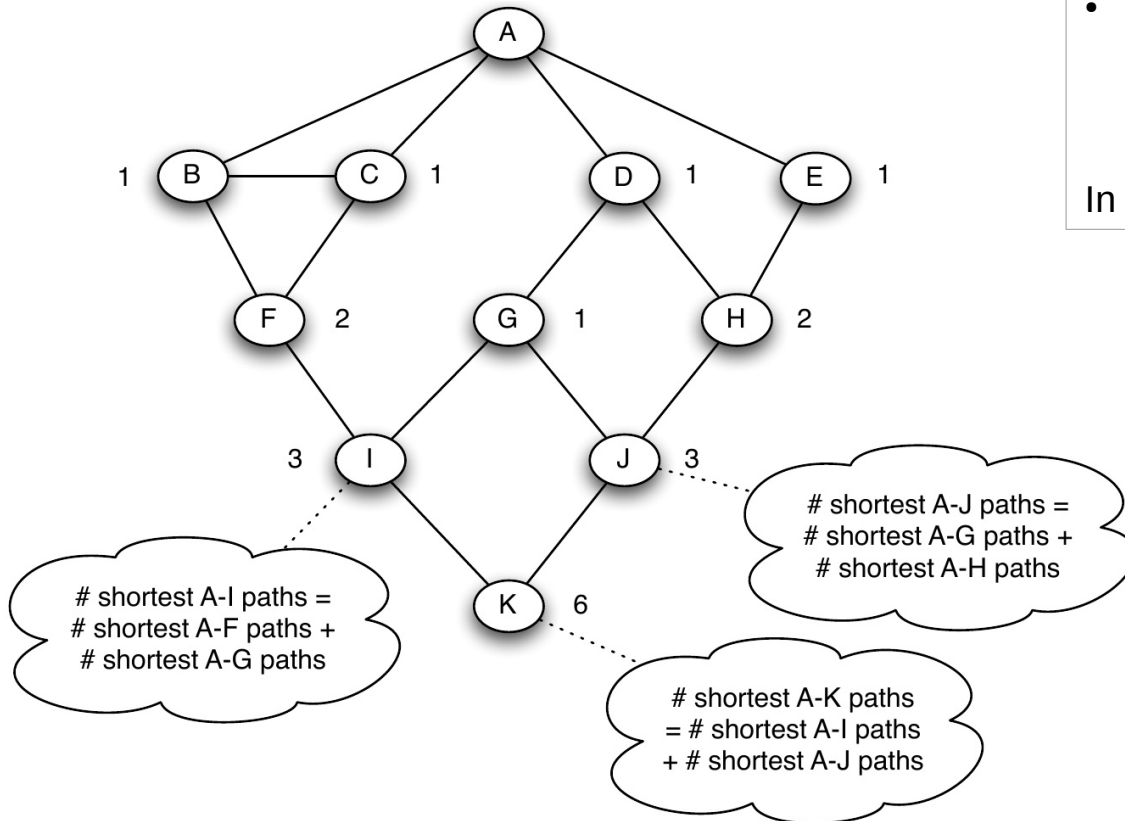

For every node u in V

- Layer the graph performing a BFS from u
- For every node v in V , $v \neq u$, sorted by layer
 - Assign to v a number $s(v)$ indicating how many shortest paths from u arrive to v
- For every node v in V , $v \neq u$, sorted by reverse layer
 - Score to distribute = $1 + \text{score from children}$
 - Add score to distribute to parent edges in proportion to $s(v)$

In the end divide all edge scores by two

Example

For every node u in V

- Layer the graph performing a BFS from u
- For every node v in V , $v \neq u$, sorted by layer
 - Assign to v a number $s(v)$ indicating how many shortest paths from u arrive to v
- For every node v in V , $v \neq u$, sorted by reverse layer
 - Score to distribute = $1 + \text{score from children}$
 - Add score to distribute to parent edges in proportion to $s(v)$

In the end divide all edge scores by two

All nodes in layer 1 get $s(v)=1$

Remaining nodes: simply add $s(\cdot)$ of their parents

Example

For every node u in V

- Layer the graph performing a BFS from u
- For every node v in V , $v \neq u$, sorted by layer
 - Assign to v a number $s(v)$ indicating how many shortest paths from u arrive to v
- **For every node v in V , $v \neq u$, sorted by rev. layer**
 - **Score to distribute = 1 + score from children**
 - **Add score to distribute to parent edges in proportion to $s(v)$**

In the end divide all edge scores by two

Nodes without children distribute a score of 1

Other nodes distribute 1 + whatever they receive from their children

Result

For every node u in V

- Layer the graph performing a BFS from u
- For every node v in V , $v \neq u$, sorted by layer
 - Assign to v a number $s(v)$ indicating how many shortest paths from u arrive to v
- For every node v in V , $v \neq u$, sorted by reverse layer
 - Score to distribute = $1 + \text{score from children}$
 - Add score to distribute to parent edges in proportion to $s(v)$

In the end divide all edge scores by two

Computed using NetworkX
(edge betweenness)

NetworkX code

```
import networkx as nx
g = nx.Graph()
g.add_edge("A", "B")
g.add_edge("A", "C")
g.add_edge("A", "D")
g.add_edge("A", "E")
g.add_edge("B", "C")
g.add_edge("B", "F")
g.add_edge("C", "F")
g.add_edge("D", "G")
g.add_edge("D", "H")
g.add_edge("E", "H")
g.add_edge("F", "I")
g.add_edge("G", "I")
g.add_edge("G", "J")
g.add_edge("H", "J")
g.add_edge("I", "K")
g.add_edge("J", "K")
nx.edge_betweenness(g, normalized=False)
```

`nx.draw_spring(g, with_labels=True)`

Exercise

Try to compute it by inspection first

*Then use the algorithm;
you should get the same results*

For every node u in V

- Layer the graph performing a BFS from u
- For every node v in V , $v \neq u$, sorted by layer
 - Assign to v a number $s(v)$ indicating how many shortest paths from u arrive to v
- For every node v in V , $v \neq u$, sorted by reverse layer
 - Score to distribute = $1 + \text{score from children}$
 - Add score to distribute to parent edges in proportion to $s(v)$

In the end divide all edge scores by two

Answer in Nearpod Draw-it
<https://nearpod.com/student/>
Access to be provided during class

Fractional values?

- In a graph with cycles, you may get **fractional values** of the edge betweenness for an edge

A: Degree

B: Closeness

C: Betweenness

D: PageRank

Summary

Things to remember

- Closeness and harmonic closeness
- Node and edge betweenness
- Practice running the Brandes-Newman algorithm on small graphs
- Write code to execute the Brandes-Newman algorithm

Practice on your own

- Compute edge betweenness on this graph

Practice on your own (cont.)

If you don't get this result, check:

<https://www.youtube.com/watch?v=uYjWbp8VC7c>

Two constructive problems

1. Sketch a graph of N nodes in which a node, which you should mark with an asterisk (*), should have betweenness approximately equal to N and closeness approximately $1/N$ for large N . Explain briefly.
2. Sketch a graph of N nodes in which a node, which you should mark with an asterisk (*), should have betweenness approximately equal to N and closeness approximately $2/N^2$ for large N . Explain briefly.

Do not use a concrete N . Use a general N , for instance by using the ellipsis (...) to denote multiple nodes.
