# Preferential Attachment (BA Model)

Social Networks Analysis and Graph Algorithms

Prof. Carlos "ChaTo" Castillo — <a href="https://chato.cl/teach">https://chato.cl/teach</a>

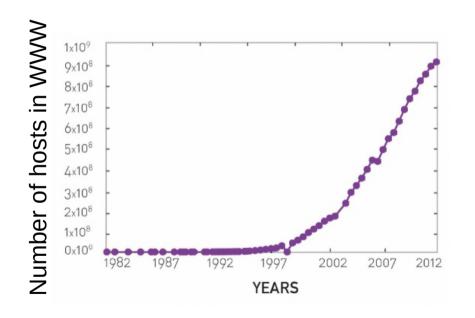

#### **Contents**

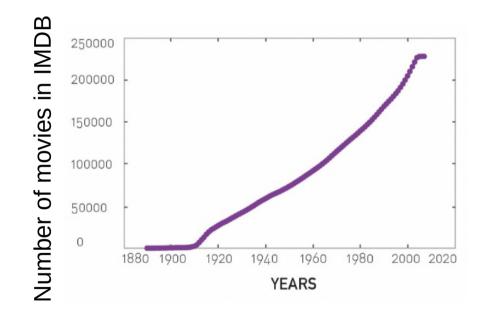

- The BA or preferential attachment model
- Degree distribution under the BA model
- Distance distribution under the BA model
- Clustering coefficient under the BA model

#### Sources

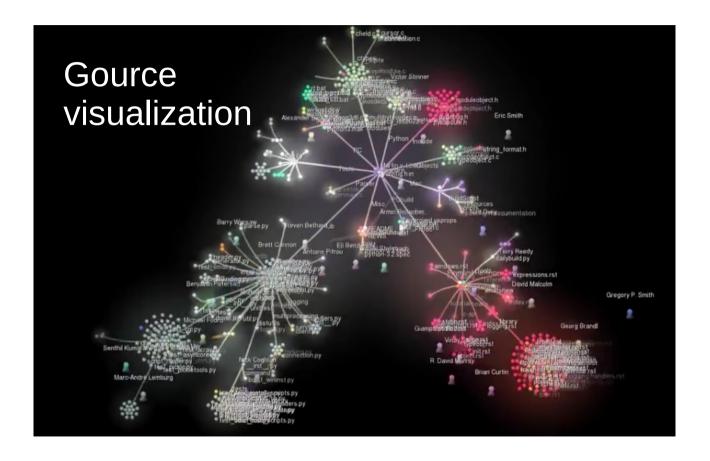

- A. L. Barabási (2016). Network Science Chapter 05
- R. Srinivasan (2013). Complex Networks Chapter 12

# The number of nodes N increases: we need models of network growth

## Growth of an Open Source Project: Python

### We have seen what but not how, or why

- Power-law degree distributions are prevalent
- We will give a possible answer to how
- For now, we will not answer why

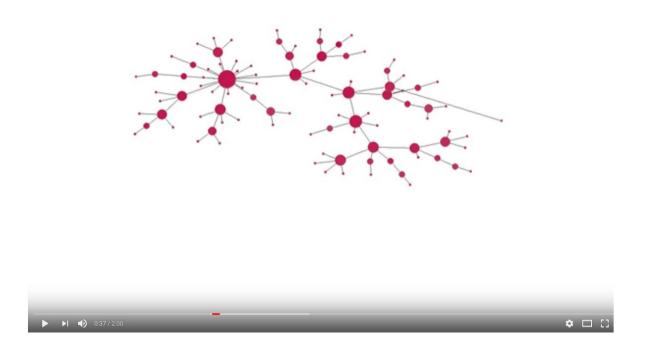

#### **Preferential Attachment**

#### Growth

- Suppose there are two web pages on a topic, one with many inlinks the other with few, which one am I most likely to link to?
- Which scientific papers are read?
- Which book authors sell more?
- Which actors are more sought after?

#### Preferential attachment simulation

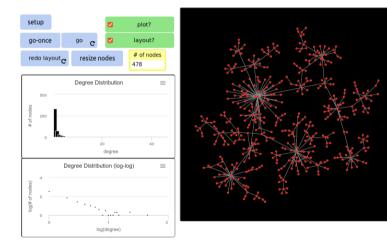

https://www.youtube.com/watch?v=4GDqJVtPEGg

#### Exercise

Answer in Nearpod Poll https://nearpod.com/student/Code to be given during class

- Execute in Netlogo Web the <u>"Preferential Attachment" program</u>:
  - Click "setup"
  - Click "go"
  - Let it run to ~500 nodes
- Guess the slope of the degree distribution

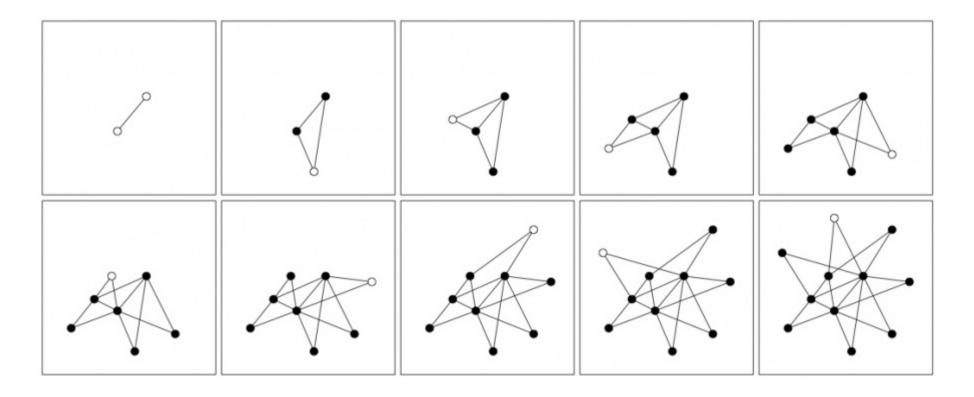

Go to netlogoweb.org/launch – run "Sample Models / Networks / Preferential Attachment"

# The Barabási-Albert (BA) model

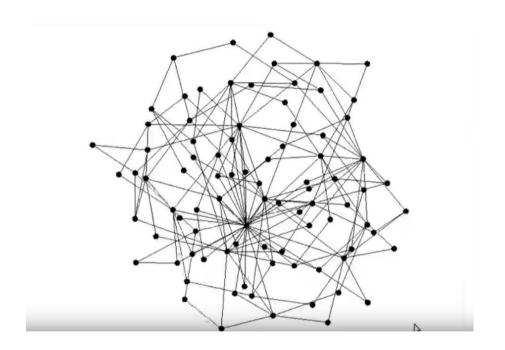

- Network starts with  $m_0$  nodes connected arbitrarily as long as their degree is  $\geq 1$
- At every time step we add 1 node
- This node will have  $m \leq m_0$  outlinks
- The probability of an existing node of degree  $k_i$  to gain one such link is  $\Pi(k_i) = \frac{k_i}{\sum_{i=1}^{N-1} k_i}$

In an ER network, 
$$\Pi(k_i) = \frac{1}{N-1}$$

# Example $(m_0 = 2; m=2)$

# Network growth with m=2

https://www.youtube.com/watch?v=wocaGeNKn7Y

# The Barabási-Albert (BA) model

- Network starts with  $m_0$  nodes connected arbitrarily as long as their degree is  $\geq 1$
- At every time step we add 1 node
- This node will have m outlinks  $(m \le m_0)$
- The probability of an existing node of degree  $k_i$  to gain one such link is  $\Pi(k_i) = \frac{k_i}{\sum_{j=1}^{N-1} k_j}$

Write the formula for N(t) and L(t): at t=0 the network has  $m_0$  nodes and L(0) links

# Summary

#### Things to remember

- Preferential attachment
- How to create a BA network step by step

#### Practice on your own

- Describe step by step in pseudocode how to create a Barabási-Albert graph with N nodes having  $m_0$  starting nodes and m outlinks per node.
- For your pseudocode to be valid, if at any point there is a randomized step, you must indicate what is the probability of each possible outcome

#### **Additional contents**

#### Video of degree distribution
