## Degree Distributions in Preferential Attachment

Introduction to Network Science Carlos Castillo Topic 12

#### Contents

- Degree distribution under the BA model
- Distance distribution under the BA model
- Clustering coefficient under the BA model

BA model means Barabási-Albert model (preferential attachment)

#### Sources

- Albert László Barabási (2016) Network Science
  - Preferential attachment follows chapter 05
- Ravi Srinivasan 2013 Complex Networks Ch 12
- Networks, Crowds, and Markets Ch 18
- Data-Driven Social Analytics course by Vicenç Gómez and Andreas Kaltenbrunner

#### Remember the BA model

- Network starts with  $m_0$  nodes connected arbitrarily as long as their degree is  $\geq 1$
- At every time step we add 1 node
- This node will have m outlinks  $(m \le m_0)$
- The probability of an existing node of degree  $k_i$  to gain one such link is  $\Pi(k_i) = \frac{k_i}{\sum_{j=1}^{N-1} k_j}$

## Degree k<sub>i</sub>(t) as a function of time

$$\frac{d}{dt}k_i = m\Pi(k_i) = m\frac{k_i}{\sum_{j=1}^{N-1}k_j}$$

$$\sum_{j=1}^{N-1}k_j = L(0) + 2m(t-1) \approx 2m(t-1)$$

$$\frac{d}{dt}k_i = \frac{mk_i}{2m(t-1)} = \frac{k_i}{2t-2} \approx \frac{k_i}{2t}$$
(For large t)

## Degree k<sub>i</sub>(t) ... continued

$$\frac{d}{dt}k_i(t) = \frac{k_i(t)}{2t}$$

Note: in exams for this course, you will **not** be asked to solve differential equations on your own

(t<sub>i</sub> is the creation time of node i)

$$\frac{1}{k_i(t)}\frac{d}{dt}k_i(t) = \frac{1}{2t}$$

$$\int_{t=t_{i}}^{t} \frac{1}{k_{i}(t)} \frac{d}{dt} k_{i}(t) dt = \int_{t=t_{i}}^{t} \frac{1}{2t} dt$$

$$\log k_{i}(t) - \log k_{i}(t_{i}) = \frac{1}{2} \log t - \frac{1}{2} \log t_{i}$$

$$\log k_i(t) = \frac{1}{2}\log t - \frac{1}{2}\log t_i + \log m$$

## Degree k<sub>i</sub>(t) ... continued

$$\log k_i(t) = \frac{1}{2} \log t - \frac{1}{2} \log t_i + \log m$$
$$k_i(t) = m \left(\frac{t}{t_i}\right)^{\frac{1}{2}}$$

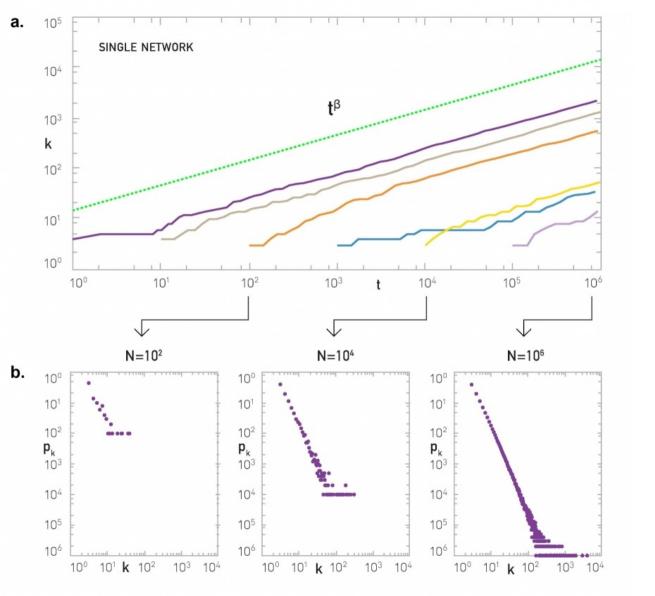

Is the degree growth linear, super-linear, or sub-linear? Intuitively, why?

## Degree k<sub>i</sub>(t) ... consequences

$$\log k_{i}(t) = \frac{1}{2} \log t - \frac{1}{2} \log t_{i} + \log m$$

$$k_{i}(t) = m \left(\frac{t}{t_{i}}\right)^{\frac{1}{2}}$$

$$\frac{dk_{i}(t)}{dt} = \frac{k_{i}(t)}{2t} = \frac{m \left(\frac{t}{t_{i}}\right)^{\frac{1}{2}}}{2t} = \frac{m}{2(t \cdot t_{i})^{\frac{1}{2}}}$$

## Simulation results

---- Model

## Degree distribution

Now let's take the derivative of the CDF to obtain the PDF

$$p_k = \frac{d}{dk} Pr(k_i \le k) = \frac{d}{dk} \left( 1 - \left( \frac{m}{k} \right)^{1/\beta} \right)$$
$$= -\frac{d}{dk} \left( \left( \frac{m}{k} \right)^{1/\beta} \right) = -m^{1/\beta} \frac{d}{dk} \left( \frac{1}{k^{1/\beta}} \right)$$
$$= \frac{1}{\beta} \frac{m^{1/\beta}}{k^{1/\beta+1}} \quad (\beta = 1/2)$$

$$=2\frac{m^2}{k^3} \qquad \qquad \blacktriangleright p(k) \propto k^{-3}$$

## Degree distribution

• Let's calculate the CDF of the degree distribution

$$Pr(k_{i} \leq k) = 1 - Pr(k_{i} > k)$$

$$= 1 - Pr\left(m\left(\frac{t}{t_{i}}\right)^{\beta} > k\right)$$

$$= 1 - Pr\left(\left(\frac{m}{k}\right)^{1/\beta} > \frac{t_{i}}{t}\right)$$

$$= 1 - \left(\frac{m}{k}\right)^{1/\beta}$$

$$= 1 - \left(\frac{m}{k}\right)^{1/\beta}$$

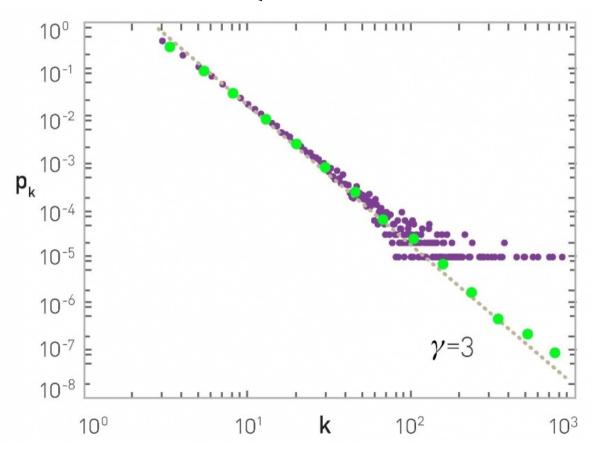

$$= 1 - \left(\frac{m}{k}\right)^{1/\beta}$$

## Degree distribution

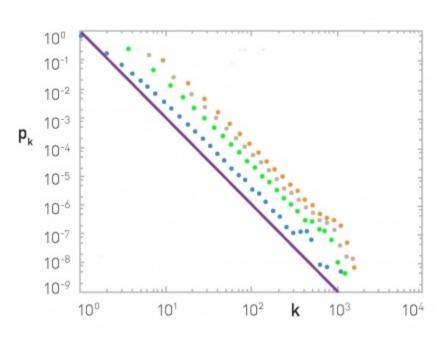

- $\beta=1/2$  is called the dynamical exponent  $\gamma=\frac{1}{\beta}+1=3$  is the power-law exponent

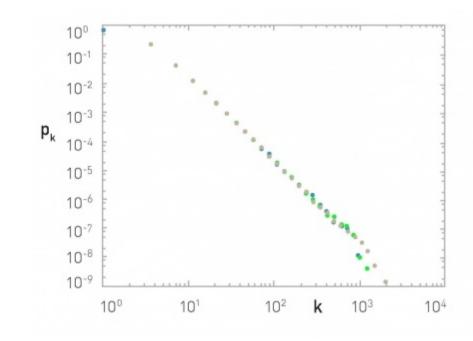

• Note that  $p(k) \approx 2m^2/k^3$ does not depend on t hence, it describes a stationary network

## Degree distribution, simulation results N=100,000 m=3

#### More simulations

Observe y is independent of m (and m<sub>0</sub>)

$$m_0 = m = 3$$
; N = 50K (blue), 100K (green), 200K (gray)

Observe p<sub>k</sub> is independent of N

The slope of the purple line is -3

#### Processes that generate scale-free networks

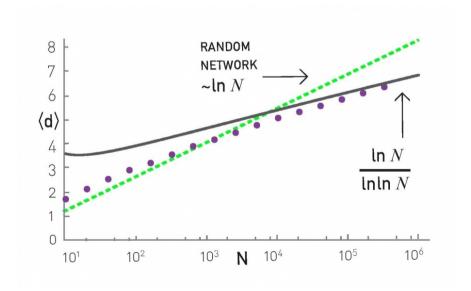

- Link-selection model step:
  - Add one new node v to the network
  - Select an existing link (u, w) at random and connect v to either u or w
- Copy model step:
  - Add one new node v to the network
  - Pick a random existing node u
  - With probability p link to u
  - With probability 1-p link to a neighbor of u

## Average distance

Distances grow slower than log N

$$\langle d \rangle \approx \frac{\log N}{\log \log N}$$

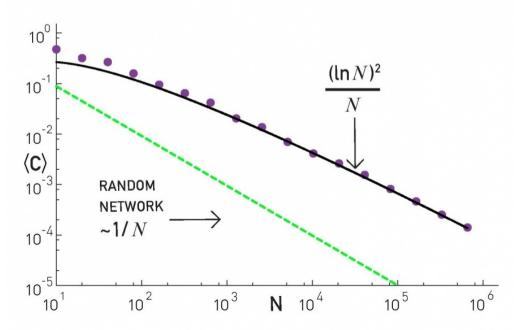

(Why: scale free network with  $\gamma = 3$ )

## Clustering coefficient

 BA networks are locally more clustered than ER networks

$$\langle C \rangle pprox \frac{(\log N)^2}{N}$$

#### Limitations of the BA model

- Predicts a fixed exponent of -3
- Assumes an undirected network, while many real complex networks are directed
- Does not consider node deletions or edge deletions which are common in practice
- Considers that all nodes are equal except for their arrival times

## Exercise: the copy model

In the copy model, start at t=1 with one node, and at every step t:

- Add one new node *v* to the network
- Pick a random existing node u
- If u has no out-links, link to u
- If *u* has out-links choose one of the following:
  - With probability p link to u
  - With probability 1-p link to one of the out-neighbors of u chosen at random
- Simulate it on paper (directed graph) for 7 nodes with p=0.5
  - Make sure you understand the model fully!
- What is N(t) and L(t)? What is  $k_i^{\text{out}}$ ?

Answer in Nearpod Draw-it https://nearpod.com/student/
Access to be provided during class

## Degree distribution in the copy model

Proven in the paper by

Kumar et al. (FOCS 2000)

$$\gamma = \frac{2-p}{1-p} \in [2,3] \text{ if } p \in [0,1/2]$$

"Stochastic models for the web graph" and developed in the advanced materials.

The copy model can generate any exponent between 2 and 3!

## Summary

## Things to remember

- Degree distribution in the BA model
- Distances and clustering coefficient in BA
- The copy model

### Practice on your own

- Try to reconstruct the derivations we have done in class
  - Try to understand every step
- Insert a small change in the model and try to recalculate what we have done

# Advanced materials: Copy model degree (not included in the exam)

In the copy model, at every step t:

- 1)Add one new node v to the network
- 2) Pick a random existing node u
- 3) With probability p link to u
- 4) With probability 1-p link to a neighbor of u

Answer in Nearpod Draw-it https://nearpod.com/student/
Access to be provided during class

- We will compute  $k_i^{\mathrm{in}}$  but first ...
- How many links on average gets node i at time t?
   In other words, what is:

$$\frac{d}{dt}k_i^{\rm in}(t)$$

• Hint: it has a term with p and a term with 1-p

- Integrate between  $t_i$  and t to obtain an expression for  $k_i(t_i)$  (we drop the "in" superscript just for simplicity during this exercise)
- Note that now  $k_i(t_i) = 0$

- Once you have a expression for  $k_i(t_i)$
- Compute  $Pr(k_i(t_i) > k)$
- Now write the cumulative distribution function of  $k_i(t_i)$
- And compute its derivative to obtain

$$p_k = Pr(k_i(t) = k) = \frac{d}{dk} Pr(k_i(t) \le k)$$

• It should show exponent  $\gamma = \frac{2-p}{1-p}$
