### The Friendship Paradox

#### Social Networks Analysis and Graph Algorithms

Prof. Carlos "ChaTo" Castillo — <a href="https://chato.cl/teach">https://chato.cl/teach</a>

#### **Contents**

- Sampling nodes and edges
- Average degree of friends

#### Sources

# Sampling a random node vs

sampling at random one of the two nodes attached to a random edge

### Exercise

#### Numerical calculation of friendship paradox

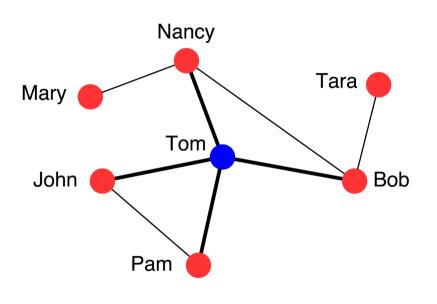

- What is the probability of selecting
   Tom if we select a random node?
- What is the probability of selecting
   Tom if we select a random edge
   and then randomly one of the two
   nodes attached to it?

# Sampling a random node vs sampling a random friend of a random node

### Average degree of friends

Average degree

$$(1+3+3+1+4+2+2)/7 = 16/7 \approx 2.29$$

- Average degree of friends of:
  - Mary: 3
  - Nancy: (1+4+3)/3 = 8/3
  - Tara: 3
  - Bob: (1+3+4)/3 = 8/3
  - Tom: (3+3+2+2)/4 = 10/4
  - John: (4+2)/2 = 3
  - Pam: (4+2)/2 = 3
  - Average degree of friends  $\approx 2.83$  (> 2.29)

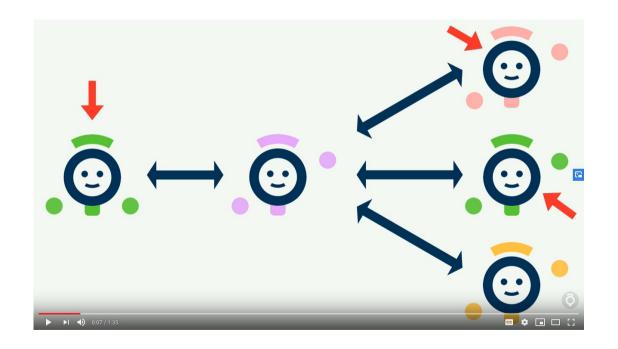

### The friendship paradox

- Take a random person x; what is the expected degree of this person? <k>
- Take a random person x, now pick one of x's neighbors, let's say
   y; what is the expected degree of y?

It is not <k>

This "paradox" is a useful vaccination strategy

# Sampling bias and the friendship paradox (1'35")

# Imagine you're at a random airport on earth

- Is it more likely to be ...

  a large airport or a small airport?
- If you take a random flight out of it ... will it go to a large airport or a small airport?

### An example of friendship paradox

- Pick a random airport on Earth
  - Most likely it will be a small airport
- However, no matter how small it is, it will have flights to big airports
- On average those airports will have much larger degree

# Exercise [B. 2016, Ex. 4.10.2] "Friendship Paradox"

- Remember  $p_k$  is the probability that a node has k "friends"
- If we randomly select a link, the probability that a node at any end of the link has k friends is  $q_k = C k p_k$  where C is a normalization factor
  - (a) Find C (the sum of  $q_k$  must be 1)

### Exercise [B. 2016, Ex. 4.10.2]

### "Friendship Paradox"

- If we randomly select a link, the probability that a node at any end of the link has k friends is  $q_k = C \ k \ p_k$  where C is a normalization factor
- $q_k$  is also the prob. that a randomly chosen node has a neighbor of degree k
  - (b) Find its expectation  $E[a_{\nu}]$  which we will call  $<\!k_F\!>$

Remember 
$$E[X] = \sum_{X_{min}}^{max} x \cdot P(X = x)$$

### Exercise [B. 2016, Ex. 4.10.2] "Friendship Paradox"

(c) Compute the expected number of friends of a neighbor of a randomly chosen node in the case below

(d) compare with the expected number of friends of a randomly chosen node

$$N = 10000$$

$$\gamma = 2.3$$

$$k_{\min} = 1$$

$$\langle k^n \rangle = C \frac{k_{\max}^{n-\gamma+1} - k_{\min}^{n-\gamma+1}}{n - \gamma + 1}$$

$$k_{\max} = 1000$$

$$C = (\gamma - 1)k_{\min}^{\gamma - 1}$$

 $C = (\gamma - 1)k_{\min}^{\gamma - 1}$ 

### **?** python™

#### Code

```
def degree moment(kmin, kmax, moment, gamma):
    C = (gamma-1.0)*(kmin**(gamma-1.0))
    numerator = (kmax**(moment-gamma+1.0) - kmin**(moment-gamma+1.0))
    denominator = (moment-gamma+1.0)
    return C * numerator / denominator
kavg = degree moment(kmin=1, kmax=1000, moment=1, gamma=2.3)
print(kavg)
3.787798988222529
ksqavg = degree moment(kmin=1, kmax=1000, moment=2, gamma=2.3)
print(ksqavq)
231.94329076177414
print(ksqavg / kavg)
```

61.23431879119234

### Summary

### Practice on your own

• Draw a small graph, and sample from that graph until you're convinced  $\langle k_F \rangle > \langle k \rangle$
