SIR on a graph

- In this simulation we assume recovery takes one timestep

- Infected nodes have thick borders

- Recovered nodes have thin borders

(a)

(b)

(c)

(d)

Social distancing

In this network, the epidemic is forced to pass through a narrow "channel" of nodes. In such a structure, even a highly contagious disease will tend to die out relatively quickly (fig 21.3 Easley+Kleinberg)

Computing infection dynamics in known graph models

SI dynamics on a graph
- Degree block approximation: all nodes with the same degree are jointly analyzed

$$i_k(t) = \frac{I_k(t)}{N_k}$$

$$i(t) = \sum_k i_k(t) p_k$$

# SI dynamics on a graph
- Degree block approximation: all nodes with the same degree are jointly analyzed

$$\frac{di_k(t)}{dt} = \Theta_k k(1 - i_k(t))\beta$$

Similar to simple SI model, except:

Θ_k is the fraction of infected neighbors of a susceptible node of degree k

Compare with simple SI model:

$$\frac{di(t)}{dt} = i(t)\langle k \rangle (1 - i(t))\beta$$

SI model on a graph:
infected as a function of time

$$i_k(t) \approx i_0 \left(1 + k \frac{\langle k \rangle - 1}{\langle k^2 \rangle - \langle k \rangle} \left(e^{t/\tau^{SI}} - 1 \right) \right)$$

What can you say about $i_k(t)$? (as a function of k,t)

$$\tau^{SI} = \frac{\langle k \rangle}{\beta \left(\langle k^2 \rangle - \langle k \rangle \right)}$$ Characteristic time, i.e., the time to infect *1/e $\simeq$ 36%* of nodes

# Higher degree nodes are more likely to become infected

$$i_k(t) = i_0 \left(1 + \frac{k\left(\langle k \rangle - 1\right)}{\langle k^2 \rangle - \langle k \rangle} \left(e^{t/\tau^{SI}} - 1 \right) \right)$$

Characteristic time

(time to infect *1/e ≃ 36%* of nodes)

$$\tau^{SI} = \frac{\langle k \rangle}{\beta \left(\langle k^2 \rangle - \langle k \rangle \right)}$$

- Random network

$$\langle k^2 \rangle = \langle k \rangle \left(\langle k \rangle + 1 \right) \Rightarrow$$

(Do it on paper)

- Scale-free network with *γ ≥ 3*

$$\langle k \rangle , \langle k^2 \rangle \ \text{are finite} \Rightarrow$$

- Scale-free network with *γ < 3*

$$\langle k^2 \rangle \xrightarrow[N \to \infty]{} \infty \Rightarrow$$

Characteristic time

(time to infect *1/e ≃ 36%* of nodes)

$$\tau^{SI} = \frac{\langle k \rangle}{\beta \left(\langle k^2 \rangle - \langle k \rangle \right)}$$

- Random network

$$\langle k^2 \rangle = \langle k \rangle \left(\langle k \rangle + 1 \right) \Rightarrow \tau^{SI}_{ER} = \frac{1}{\beta \langle k \rangle}$$

- Scale-free network with *γ ≥ 3*

$$\langle k \rangle, \langle k^2 \rangle \text{ are finite} \Rightarrow \tau^{SI}_{BA} \text{ is finite}$$

- Scale-free network with *γ < 3*

$$\langle k^2 \rangle \xrightarrow[N \to \infty]{} \infty \Rightarrow$$

What happens?

Characteristic time

(time to infect *1/e ≃ 36%* of nodes)

$$\tau^{SI} = \frac{\langle k \rangle}{\beta \left(\langle k^2 \rangle - \langle k \rangle \right)}$$

- Random network

$$\langle k^2 \rangle = \langle k \rangle \left(\langle k \rangle + 1 \right) \Rightarrow \tau^{SI}_{ER} = \frac{1}{\beta \langle k \rangle}$$

- Scale-free network with *γ ≥ 3*

$$\langle k \rangle, \langle k^2 \rangle \text{ are finite} \Rightarrow \tau^{SI}_{BA} \text{ is finite}$$
- Scale-free network with *γ < 3*

$$\langle k^2 \rangle \xrightarrow[N \to \infty]{} \infty \Rightarrow \lim_{N \to \infty} \tau^{SI}_{BA} = 0$$

Vanishing characteristic time

$$\tau^{SI} = \frac{\langle k \rangle}{\beta \left(\langle k^2 \rangle - \langle k \rangle \right)}$$

- If $\lim_{N \to \infty} \frac{\langle k \rangle}{\langle k^2 \rangle} = 0$ the characteristic time goes to 0

- Networks with skewed degree distributions allow infections with the same β to spread faster

SIS dynamics on a graph

Similar to SI dynamics but allowing recovery

$$\frac{di_k(t)}{dt} = k(1 - i_k(t))\Theta_k \beta - \mu i_k(t) \qquad \tau^{SIS} = \frac{\langle k \rangle}{\beta \langle k^2 \rangle - \mu \langle k \rangle}$$

If people recover quickly, $\tau < 0$ and the infection dies out ... unless $\langle k^2 \rangle \to \infty$

Epidemic threshold

- A key quantity is the spreading rate $\lambda = \dfrac{\beta}{\mu}$

- The critical spreading rate λ_c called the epidemic threshold, is such that $\tau > 0$

- Spreading rate larger than epidemic threshold:
  - infection becomes endemic

- Spreading rate smaller than epidemic threshold:
  - Infection dies out

Epidemic threshold

- A key quantity is the spreading rate $\lambda = \dfrac{\beta}{\mu}$

- The critical spreading rate λ_c called the epidemic threshold, is such that $\tau > 0$

Compute the epidemic threshold β/μ for an ER graph where $\left\langle k^2 \right\rangle = \left\langle k \right\rangle \left(\left\langle k \right\rangle + 1 \right)$

Begin from: $\tau^{SIS} = \dfrac{\left\langle k \right\rangle}{\beta \left\langle k^2 \right\rangle - \mu \left\langle k \right\rangle}$ and use that $\tau^{SIS} > 0$

Epidemic threshold in an ER graph

$$\tau = \frac{\langle k \rangle}{\beta(\langle k \rangle \left(\langle k \rangle + 1 \right)) - \mu \langle k \rangle}$$

$$\tau = \frac{1}{\beta(\langle k \rangle + 1) - \mu}$$

$$\tau > 0 \Rightarrow \beta(\langle k \rangle + 1) - \mu > 0$$

$$\frac{\beta}{\mu} > \dots$$

Epidemic threshold in an ER graph

$$\tau = \frac{\langle k \rangle}{\beta(\langle k \rangle \, (\langle k \rangle + 1)) - \mu \, \langle k \rangle}$$

$$\tau = \frac{1}{\beta(\langle k \rangle + 1) - \mu}$$

$$\tau > 0 \Rightarrow \beta(\langle k \rangle + 1) - \mu > 0$$

$$\frac{\beta}{\mu} > \frac{1}{\langle k \rangle + 1}$$

Epidemic threshold in ER graph

$$\lambda_c = \frac{1}{\langle k \rangle + 1}$$

If this holds, the infection becomes endemic

Any less infectious pathogen or one that has faster recovery causes the infection to die out
Epidemic threshold in a scale-free network

$$\tau^{SIS} = \frac{\langle k \rangle}{\beta \langle k^2 \rangle - \mu \langle k \rangle} > 0 \Rightarrow \frac{\beta}{\mu} > \frac{\langle k \rangle}{\langle k^2 \rangle} = \lambda_c$$

Epidemic threshold
in BA graph

- In a scale-free network with *γ < 3*

$$\langle k^2 \rangle \xrightarrow[N \to \infty]{} \infty \Rightarrow \lim_{N \to \infty} \tau^{SIS} = 0$$

Infected (in the limit) as a function of the epidemic threshold

Two key results for SI and SIS models on a BA graph

In a large scale-free network with $\gamma < 3$

- An infection may reach everybody in a very short time: $\tau = 0$

- An infection may become endemic even if it is not very contagious and even if people recover fast: $\lambda_c = 0$

Summary

Things to remember

- Degree block approximation
- Epidemic thresholds in scale-free networks
